

# A Statistical Analysis of Error in MPI Reduction Operations

**Samuel D. Pollard** and Boyana Norris

11 November, 2020

- 1 Overview of Floating-Point Arithmetic
- 2 The State Space of MPI Reduction Operations
- 3 Analytical Bounds
- 4 Empirical Results
- 5 Nekbone: A Case Study
- 6 Conclusion

# Floating-Point Arithmetic Is Not Associative

- ▶ Let  $\oplus$  be floating-point addition
- ▶  $0.1 \oplus (0.2 \oplus 0.3) = 0x1.3333333333334p-1$
- ▶  $(0.1 \oplus 0.2) \oplus 0.3 = 0x1.3333333333333p-1$
- ▶ Worse error when the magnitudes are different

```
a <- 1.0
b <- 1e16
c <- -1e16
(a + b) + c = 0
a + (b + c) = 1
```

What is the effect of assuming associativity for parallel summation error?

## Bound on Relative Error

- ▶ Let  $\text{op} \in \{+, -, \div, \times\}$ , and  $\odot$  be its corresponding floating point operation. Then

$$x \text{ op } y = (x \odot y)(1 + \delta) \text{ where } |\delta| \leq \epsilon. \quad (1)$$

- ▶ This holds only for  $x \odot y \neq 0$  and normal (not subnormal)
- ▶ For double-precision  $\epsilon = 2^{-53}$

- 1 Overview of Floating-Point Arithmetic
- 2 The State Space of MPI Reduction Operations
- 3 Analytical Bounds
- 4 Empirical Results
- 5 Nekbone: A Case Study
- 6 Conclusion

# MPI Reduce

- ▶ Assume an array  $A$  of size  $n$
- ▶ Reduce  $A$  to a single value with a binary operation
  - Interesting ones are MPI\_SUM and MPI\_PROD
- ▶ Distribute  $A$  across MPI ranks (each  $p_k$ )
- ▶ Unspecified but typically deterministic reduction order when run on the same architecture and topology

How many ways are there to do this reduce?

# How many ways are there to do this reduce?

- ▶ Depends on how we define acceptable reduction strategy
- ▶ We list four families
  - 1 Canonical Left-Associative (Canon)
  - 2 Fixed Order, Random Association (FORA)
  - 3 Random Order, Random Association (RORA)
  - 4 Random Order, Left-Associative (ROLA)

# 1. Canonical Left-Associative

- ▶ Left-associative
- ▶ Unambiguous: one reduction strategy
- ▶ No freedom to exploit parallelism

```
double acc = 0.0;
for (i = 0; i < N; i++) {
    acc += A[i];
}
```

# Parallel Reductions

To look at parallelism, we start with the MPI Standard

## The MPI Standard is Flexible

*The operation  $op$  is always assumed to be associative. All predefined operations are also assumed to be commutative. . . However, the implementation can take advantage of associativity, or associativity and commutativity, in order to change the order of evaluation. This may change the result of the reduction for operations that are not strictly associative and commutative, such as floating-point addition. [4]*

## If Commutativity Is Required

*The order of operands is fixed and is defined to be in ascending, process rank order, beginning with process zero. The order of evaluation can be changed, taking advantage of the associativity of the operation. [4]*

## 2. Fixed Order, Random Association (FORA)

- ▶ Let's start with the `commute = false` case
- ▶ Assume inorder tree traversal
- ▶ Combinatorially well-known example of a Catalan number
- ▶ Given array of size  $n$ ,

$$C_n = \frac{(2n)!}{(n+1)!n!}$$

different combinations.

- ▶ We call these *associations*

## Example Summation

- With the commutative but nonassociative operator  $\oplus$ ,  $r_1 = r_2$  but  $r_2 \neq r_3$ .

$$r_1 = a \oplus (b \oplus c)$$

$$r_2 = (c \oplus b) \oplus a$$

$$r_3 = c \oplus (b \oplus a)$$

### 3. Random Order, Random Association (RORA)

- ▶ This family describes the default if we call MPI\_Reduce
- ▶ Less than  $C_n$  because of commutativity
- ▶ Less well-known, but still solved combinatorial problem [3]

$$g_n = (2n - 3)!!$$

where  $!!$  is the double factorial (in this case on odd integers). That is,  
 $(2n - 3)!! = 1 \times 3 \times 5 \times \cdots \times 2n - 3$ .

## 4. Random Order, Left Associative (ROLA)

- ▶ Shuffle array first, then sum canonically
- ▶ Main purpose is to compare with previous work by Chapp et al. [2]

## Generating Random Binary Trees

- ▶ Rémy's Procedure
- ▶ Given a tree with  $n - 1$  leaf nodes, pick one of the nodes randomly ( $x$ )
- ▶ Add a new node  $k$  one of two ways:

- 1 Overview of Floating-Point Arithmetic
- 2 The State Space of MPI Reduction Operations
- 3 Analytical Bounds**
- 4 Empirical Results
- 5 Nekbone: A Case Study
- 6 Conclusion

# Absolute Error

Let  $\sum^{\oplus}$  be floating point sum,  $S_A$  be the true sum.

Wilkinson back in '63 proved summation error is bounded by

$$\left| \sum_{k=1}^{\oplus n} A_k - S_A \right| \leq \epsilon(n-1) \sum_{k=1}^n |A_k| + O(\epsilon^2). \quad (2)$$

# Estimating Error

From Robertazzi & Schwartz [5] if we assume

- 1  $A_k \sim U(0, 2\mu)$  or  $\exp(1/\mu)$ .
- 2 Floating point errors are independent, distributed with mean 0, variance  $\sigma^2$
- 3 Summation ordering is random

Then the relative error is approximately

$$\frac{1}{3}\mu^2 n^3 \sigma_e^2. \quad (3)$$

We'll substitute values in for (2) and (3) later

- 1 Overview of Floating-Point Arithmetic
- 2 The State Space of MPI Reduction Operations
- 3 Analytical Bounds
- 4 Empirical Results**
- 5 Nekbone: A Case Study
- 6 Conclusion

# Left and Random Associativity (ROLA vs. RORA)

- ▶ ROLA is a biased sum
- ▶ worst RORA has smaller error than canonical

$n = 50,000$ ,  $|A| = 2,000,000$ ,  $A_k \sim U(0, 1)$

# Fixed and Random Ordering (FORA vs. RORA)

- ▶ Almost identical
- ▶ Error mainly from adding small number to large partial-sum
- ▶ Notice canonical would be off this chart

$n = 50,000$ ,  $|A| = 2,000,000$ ,  $A_k \sim U(0, 1)$

# RORA with Different Distributions

- ▶  $U(-1, 1)$  worst because of catastrophic cancelation

$n = 50,000$ ,  $|A| = 2,000,000$

# Empirical Results for Uniform(0,1), Tabulated

- ▶  $\overline{\phantom{x}}$  is average
- ▶ Robertazzi Estimator matches closely with observed data

Distribution	Measurement	Relative Error
U(0, 1)	$\overline{\text{RORA}}$	$6.702 \times 10^{-16}$
U(0, 1)	$\max(\text{RORA})$	$4.073 \times 10^{-15}$
U(0, 1)	$\overline{\text{ROLA}}$	$1.282 \times 10^{-14}$
U(0, 1)	Canonical	$1.062 \times 10^{-14}$
U(0, 1)	Analytical	$1.776 \times 10^{-8}$
U(0, 1)	Robertazzi	$6.848 \times 10^{-16}$
	machine $\epsilon$	$1.110 \times 10^{-16}$

# Error Estimators for Uniform $(-1,1)$

- ▶ Recap of previous figures;
- ▶ Error is greater for  $U(-1, 1)$

Distribution	Measurement	Relative Error
$U(-1, 1)$	$\overline{\text{RORA}}$	$2.104 \times 10^{-14}$
$U(-1, 1)$	$\max(\text{RORA})$	$4.824 \times 10^{-14}$
$U(-1, 1)$	$\overline{\text{ROLA}}$	$8.358 \times 10^{-12}$
$U(-1, 1)$	Canonical	$6.124 \times 10^{-12}$
$U(-1, 1)$	Analytical	$7.951 \times 10^{-7}$
	machine $\epsilon$	$1.110 \times 10^{-16}$

- 6 Conclusion

# Nekbone

- ▶ Nekbone is a computational fluid dynamics proxy app
- ▶ We look at residual of conjugate gradient
- ▶ We use SimGrid [1] to try out 16 different allreduce algorithms

## Nekbone (Cont.)

- ▶ Only four results across 16 algorithms
- ▶ Most differ only by the last few bits

Allreduce Algo. Rank	Residual
Best (smp_rsag)	$1.616\,306\,278\,792\,575 \times 10^{-8}$
Default	$14.082\,603\,491\,982\,575 \times 10^{-8}$
Worst	$14.082\,603\,491\,982\,647 \times 10^{-8}$
Other	$14.082\,603\,491\,982\,618 \times 10^{-8}$

- 3 Analytical Bounds
- 4 Empirical Results
- 5 Nekbone: A Case Study
- 6 Conclusion

# Future Work & Conclusion

## Future Work

- ▶ Generate more realistic reduction trees, realistic random input, expose more nondeterminism in SimGrid

## In Conclusion

- ▶ Looked at error for four different families of reduction strategies
- ▶ Reduction tree shape has greater effect than how the array is ordered
- ▶ Despite large state space, realistic programs generate a tiny subset of what is permitted
